• Contributions:

- 1. We propose a series of efficient softmax alternatives that unify the ideas of pointer network, reranker, multiple embeddings, and vocabulary partitioning.
- 2. We evaluate the proposed softmax alternatives in text completion tasks and summarization tasks using various metrics to identify where our methods improve the most.
- 3. Our experiments indicate pointer networks and our proposed alternatives can still improve the modern transformer-based LMs. By breaking the softmax bottleneck, our methods learn sometimes to copy the context words to reduce generation hallucination and sometimes exclude the context words to reduce the repetition.

Figure 3: This table shows that dynamic partitioning are very helpful in terms of perplexity. Lower perplexity is better

Summarization Experiments

Improve BookSum more

• Probably because the names in narrative text are usually locally defined

Figure 4: The performance on test sets of four summarization datasets.

Conclusion

Methods: Softmax-CPR

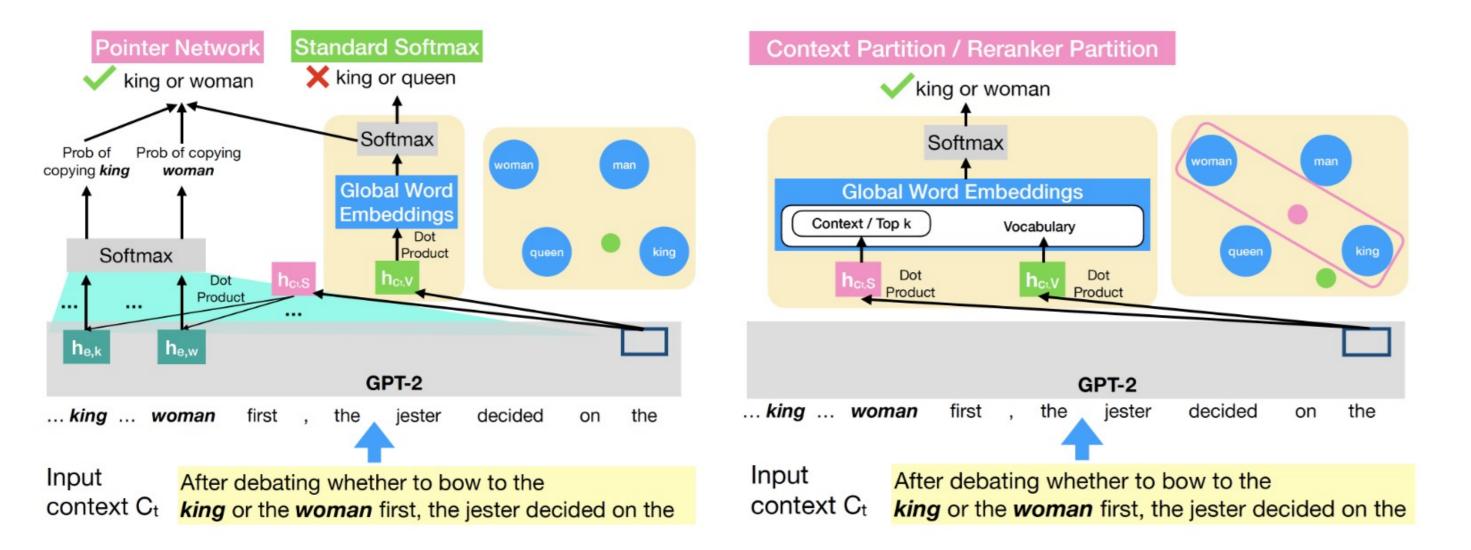

Figure 1: Left: Illustration of the softmax bottleneck and pointer network. Right: We simplify the pointer network / reranker by using another embedding $\mathbf{h}_{c_t,S}$ for the words in the context / the top-k likely words.

1. We propose softmax-CPR and softmax-CEPR, which unify the ideas of the pointer network, reranker, and mixture of softmax (MoS) (a) Alleviate hallucination and repetition problem (b) mostly by learning to copy the words from context properly 2. Pointer networks significantly boost summarization factuality (a) their improvements mainly come from breaking the softmax bottleneck rather than its attention mechanism

(b) Softmax-CPR could bring even more improvements
